## Jump Registers

# Jump Registers

Jump Control=0

## Jump Registers

## Jump Registers

Jump Control=0

## Jump Registers

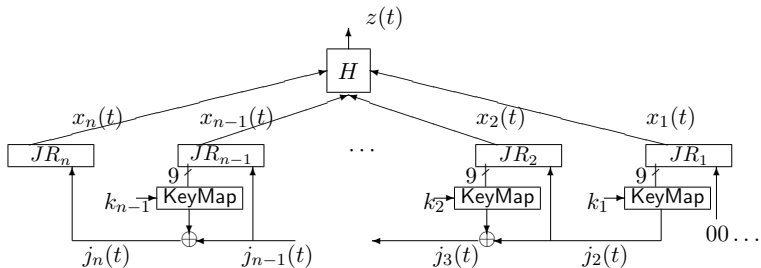

Jump Control=1

Jump Index=12

# Description of Pomaranch

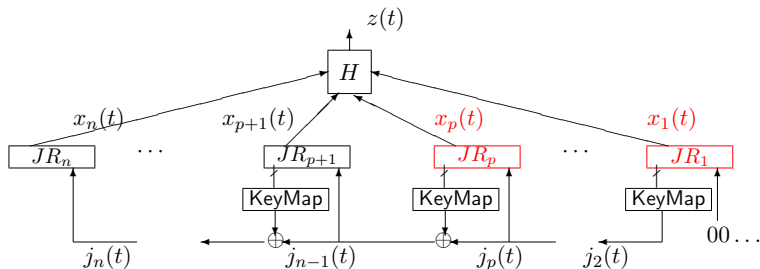

- $n$  jump registers  $JR_1, \dots, JR_n$  of length  $L$ .
- Jump sequence  $j_2, \dots, j_n$  used to clock jump registers.
- KeyMap, key-dependent function,  $f : \mathbb{F}_2^9 \mapsto \mathbb{F}_2$ .
- Filter function  $H$ .

# Different Designs

- 5 different proposals for Pomaranch ciphers.
- 3 different design ideas:
  - 1 Same jump register, linear filter function.
  - 2 Different jump registers, linear filter function.
  - 3 Different jump registers, non-linear filter function.

## Period of Jump Registers

- Period of  $JR_1$  is denoted  $T_1$ ,  $T_1 = 2^L - 1$ .
- Period for register  $JR_p$  is  $T_p = T_1^p \approx 2^{pL}$ .

Hence

$$x_i(t) = x_i(t + T_1^i), \quad 1 \leq i \leq p.$$

- Useful for  $p$  such that  $T_1^p < 2^{|K|}$ ,  $|K| = \text{Key size}$ .

## Period of Jump Registers

Take samples at time  $t$  and  $t + T_1^p$ :

$$z(t) + z(t + T_1^p) = H(x_1(t), \dots, x_n(t)) + H(x_1(t + T_1^p), \dots, x_n(t + T_1^p)).$$

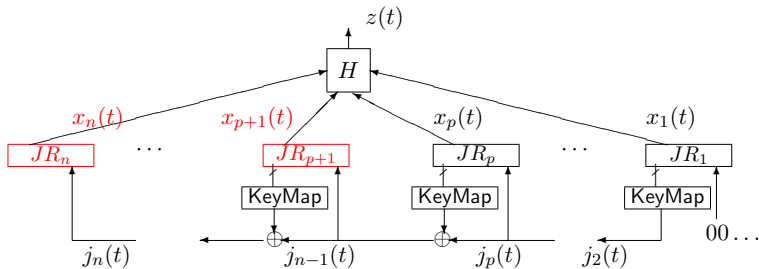

- Linear  $H$ :

$$z(t) + z(t + T_1^p) = \sum_{i=p+1}^n x_i(t) + x_i(t + T_1^p).$$

- Non-linear  $H$ :  $H(t)$  and  $H(t + T_1^p)$  have  $p$  inputs  $x_1, \dots, x_p$  in common,  $0 \leq p \leq n$ .

$$\Pr(z(t) + z(t + T_i^p) = 0) = \frac{1}{2}(1 - \delta), \quad -1 \leq \delta \leq 1.$$

# Linear Approximation of $JR_{p+1}, \dots, JR_n$

For  $JR_l, p+1 \leq l \leq n$ , search for a set  $\mathcal{A}$  of size  $w$  such that

$$\Pr\left(\sum_{i \in \mathcal{A}} x_l(t+i) = 0\right) = \frac{1}{2}(1 - \varepsilon), \quad -1 \leq \varepsilon \leq 1,$$

## Design Idea 1: Linear $H$ , same registers

- Linear approximation of one register, (applies to all registers);
- Samples at time  $t$  and  $t + T_1^p$ .

$$\begin{aligned} & \sum_{i \in \mathcal{A}} z(t+i) + z(t+i+T_1^p) = \\ &= \sum_{j=p+1}^n \sum_{i \in \mathcal{A}} (x_j(t+i) + x_j(t+i+T_1^p)). \end{aligned}$$

- Bias of  $\sum_{i \in \mathcal{A}} x_i(t+i)$  is  $\varepsilon$ , we have  $2(n-p)$  such relations

$$\varepsilon_{tot} = \varepsilon^{2(n-p)}$$

- $1/\varepsilon_{tot}^2$  samples needed to distinguish the cipher from a truly random source.

## Design Idea 1: Linear $H$ , same registers

### Theorem

*The computational complexity and the number  $N$  of keystream bits needed to reliably distinguish the Pomaranch family of stream ciphers using a linear filter function and  $n$  jump registers of the same type is upper bounded by*

$$N \leq T_1^p + \frac{1}{\varepsilon^{4(n-p)}}, \quad p > 0,$$

*where  $\varepsilon$  is the bias of the best linear approximation of the jump register.*

- Pomaranch v1 (128 bit): Keystream and Complexity= $2^{71}$ .
- Pomaranch v2 (80 bit): Keystream and Complexity= $2^{56}$ .
- (128 bit): Keystream and Complexity= $2^{77}$ .

## Design Idea 2: Linear $H$ , Different Registers

- Samples at time  $t$  and  $t + T_1^p$ .
- Linear approximation for all registers jointly.
- Bias for the approximation of register  $i$  is  $\varepsilon_i$ , total bias is given by

$$\varepsilon_{tot} = \prod_{i=p+1}^n \varepsilon_i^2.$$

## Design Idea 2: Linear $H$ , Different Registers

### Theorem

*Assuming there is a linear relation that is biased in all registers. The computational complexity and the number  $N$  of keystream bits needed to reliably distinguish the Pomaranch family of stream ciphers using a linear filter function and  $n$  jump registers of different types is upper bounded by*

$$N \leq T_1^p + \frac{1}{\prod_{i=p+1}^4 \varepsilon_i}, \quad p > 0,$$

*where  $\varepsilon_i$  is the bias of jump register  $JR_i$ .*

- Pomaranch v3 (128 bit): Keystream and Complexity =  $2^{126}$ .  
(Without frame length restriction)

## Design Idea 3: Nonlinear $H$ , Different Registers

- Consider the case, (can easily be extended), when the filter function  $H$  can be written on the form

$$H(x_1, \dots, x_n) = G(x_1, \dots, x_{n-1}) + x_n.$$

- $G(t)$  and  $G(t + T_1^p)$  have  $p$  inputs  $x_1, \dots, x_p$  in common,

$$\Pr(z(t) + z(t + T_i^p) = 0) = \frac{1}{2}(1 - \delta), \quad -1 \leq \delta \leq 1.$$

- Find linear approximation for  $JR_n$ .

## Design Idea 3: Nonlinear $H$ , Different Registers

$$H(x_1, \dots, x_n) = G(x_1, \dots, x_{n-1}) + x_n. \quad (1)$$

### Theorem

*The computational complexity and the number  $N$  of keystream bits needed to reliably distinguish the Pomaranch family of stream ciphers using a filter function of the form (1) is upper bounded by*

$$N \leq T_1^p + \frac{1}{(\varepsilon^2 \delta w)^2}.$$

*where  $\varepsilon$  is the a biased approximation of weight  $w$  of register  $JR_n$  and  $\delta$  is the bias of*

$$G(x_1(t), \dots, x_{n-1}(t)) + G(x_1(t + T_1^p), \dots, x_{n-1}(t + T_1^p)).$$

- Pomaranch v3 (80 bit): Keystream and Complexity =  $2^{71}$ .

## Attack II: Square Root Resynchronization Attack

- Divide the internal state into two parts,

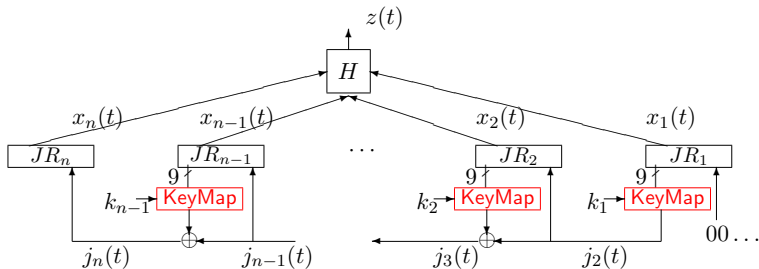

$$State = (State_K, State_{K+IV}).$$

$State_K$  only holds the key.

$State_{K+IV}$  depends on both key and  $IV$ .

- If key size  $|K| > |State_{K+IV}|/2$ , attack succeeds with complexity below exhaustive key search.
- One attack scenario:
  - Fixed key.
  - One long keystream sequence from one  $IV$ .
  - Intercept ciphertexts from many  $IV$ s, knowing  $l$  plaintext bits of every ciphertext.
  - Goal is to recover more of the plaintext for one message.

# Square Root Resynchronization Attack on Pomaranch

- $\text{KeyMap}$ , is key dependent but independent of IV.

# Square Root Resynchronization Attack on Pomaranch

- Samples taken as,  $S(t) = (z(t), z(t+1), \dots, z(t+nL-1))$ .
- Fixed key defines state graph of size  $(2^L - 1)^n \approx 2^{nL}$ .
- Store large amount of samples from  $IV_0$  in table.
- Find  $IV_c$ , such that  $S_{IV_c}(t_c) = S_{IV_0}(t_0)$ .

# Attack Complexities

- Assume we have  $2^{\beta nL}$  samples from  $IV_0$ .
- We need samples from  $2^{(1-\beta)nL}$  different IVs to find collision.
- Time:
  - Sort table  $\beta nL 2^{\beta nL}$ .
  - Search in table  $\beta nL 2^{(1-\beta)nL}$
- Memory:  $nL 2^{\beta nL}$

# Results

		Attack I	Attack II
		Keystream/Compl.	Memory/IVs/Compl.
Pomaranch v1	128 bit	$2^{71} / 2^{71}$	$2^{67} / 2^{63} / 2^{63}$
Pomaranch v2	80 bit	$2^{56} / 2^{56}$	$2^{45} / 2^{42} / 2^{42}$
	128 bit	$2^{77} / 2^{77}$	$2^{67} / 2^{63} / 2^{63}$
Pomaranch v3	80 bit	$2^{71} / 2^{71}$	$2^{58} / 2^{54} / 2^{54}$
	128 bit	$2^{126} / 2^{126}^*$	$2^{71} / 2^{98} / 2^{104}$

\* Without frame length restriction.

# Conclusions

- Presented the best distinguisher so far on all version and variants of Pomaranch in terms of computational complexity.
- Presented a general resynchronization attack that works for all ciphers where  $|K| > |State_{K+IV}|/2$ .
- First attack presented on Pomaranch Version 3.
